Sample

This study is based on a web survey for which the survey firm Respondi sampled adult respondents from four different countries: USA, Germany, Poland, Sweden. Respondi uses both online channels and telephone interviews to recruit members of their access panel. The main survey was in the field from April 2021 to June 2021 following a pretest phase with 100 respondents per country. We employed simple quotas on education, age, and gender in line with population characteristics of the respective countries. Our final sample includes 8,000 respondents (2000 per country) of which 7,828 participated in the MDG and 7,785 participated in the TDG; 7,722 respondents participated in both games.

After the completion of the survey, 100 primary respondents per country were randomly selected and received the share of the money they decided to keep; 100 further respondents of the same country and matching in subjective social status as presented in the MDG and TDG (see Figure A1) were selected and received the share of the money the primary respondent decided to share. Before answering the experimental tasks, all respondents were informed about this payment mechanism.

Money Dictator Game (MDG)

You receive 15 USD. You can give any percentage between 0% and 100% to a participant in a similar study, leaving the remainder of the money to yourself. We will let the other participant know how much money he/she has been given.

The other participant has been asked the same questions as you. When asked about his/her standing on the ladder that represents the society in the United States, he/she has placed himself/herself on the lower rungs (1-3) of society.

What is your decision?

Click on the track and use the slider which then appears to adjust your choice.

Your current choice means you will give **95% (14.25 USD)** to the other participant and keep **5% (0.75 USD)** to yourself.

Percentage I will give to the other participant

Time Dictator Game (TDG)

You have to complete the previously described task for 5 minutes. You can give any percentage of time between 0% and 100% to a participant in a similar study, while you have to complete the task for the remainder of the time. We will let the other participant know how much time he/she has been given.

The other participant has been asked the same questions as you. When asked about his/her standing on the ladder that represents the society in the United States, he/she has placed himself/herself on the middle rungs (5-7) of society.

What is your decision?

Click on the track and use the slider which then appears to adjust your choice.

Your current choice means the other participant has to fulfill the task for **27% of the time (1:21 minutes)** while you will fulfill the task for **73% of the time (3:39 minutes)**.

Percentage the other participant will complete the task

Please click the black square the whole time. Your time (00:30 minutes) starts with the first click. You will be forwarded automatically as soon as you have completed the task.

Click the black square for 0:15 more minutes. Paused because of inactivity!

Fig. A1. Experimental setups of the MDG (left) and TDG (right).

Variables

We have constructed a composite measure of social status, equaling the standardized average of respondents' education (ISCED), occupational prestige (SIOPS), and the decile of the household OECD-equivalized income. Missing values for income (n=159) and job prestige (n=3889, excluding Sweden) were imputed using stochastic regression. Income was regressed on age, gender, education, employment situation, and household size; the regression model of job prestige additionally included income. The composite measure of social status for Sweden does not include job prestige, as the automatic assignment of ISCO codes and SIOPS values to the jobs (using the EurOccupations Database) was not possible. Subjective socioeconomic status was measured using the McArthur Scale. Respondents were asked to place themselves on an 11-rung ladder representing their country's society ("Think of a ladder as representing where people stand in the [country]. At the top of the ladder (11) are the people who are the best off – those who have the most money, most education and best jobs. At the bottom (1) are the people who are the worst off – who have the least money, least education and the worst jobs or no jobs. The higher up you are on this ladder, the closer you are to people at the very top and the lower you are, the closer you are to people at the very bottom. Where would you place yourself on this ladder?"). For descriptives on samples and status variables see Table A1.

Statistical Analyses

We employ Cragg hurdle models to analyze our data. The Cragg model is a two-part model, combining a selection model with an outcome model and thus separating the decisions of sharing money or time into two-step processes. It comprises a separate estimate of binary probit model and a truncated regression. The Cragg hurdle models outperform standard OLS for all models according to Akaike's and Schwarz's Bayesian information criteria. We further checked whether seemingly unrelated regression equations would affect our significance levels; this was not the case.

We run a pooled model where we employ cluster robust standard errors, and separate models for each country. To check robustness (see Tables A5 to A14), we run 1) a model where we removed the top and bottom 5% of observations regarding SES, 2-4) models using the separate indicators of SES, i.e., education, income, and job prestige, 5-8) models using different combinations of these indicators to construct the composite measure, 9-10) and models using the separate indicators without any imputed values. This allows us to check whether the results are driven by outliers or specific status dimensions.

Overall, the main results of our paper are relatively stable across the different model specifications. For the MDG, we find significant positive effects of all measures of SES in the pooled model, in Germany and in Sweden; in the US, all measures except job prestige excluding imputed values are positive and significant. In Poland, we find effects of job prestige (both imputed and not imputed) and the composite measures which includes all measures (10%), and the composite measure including income and job prestige (5%).

In the TDG, we find significant negative effects of all measures of SES in Sweden. In the pooled model and in Germany, income has a negative but non-significant effect; in the US and Germany, job prestige excluding imputed values does not show a significant negative effect. While we did not report a significant and negative effect for the composite measure in Poland, we find significant (at least 5%) negative effects of education and job prestige, as well as the composite measure which does not include income.

All results refer to the second stage in the Cragg models. At the first stage, measures of objective social status do not seem to play a role when deciding whether to give any money/time at all.

Table A1: Descriptives of sample and status variables (mean, standard deviation, minimum/maximum):

	Germany	Poland	Sweden	US
Composite	-0.0467	0.032	0.039	0.027
